

Neo Library is a simple web app I built using Django to act like a basic online library system. It lets you store and view books, and also organise them by authors and genres. The idea was to create something that feels like a real library, where books are properly structured and easy to manage. The project works by using Django's normal structure of models, views, and templates. The models handle the data, like books, authors, and genres, and how they are connected. The views are responsible for getting that data and sending it to the pages, and the templates are just the HTML pages that show everything in the browser. I also used Django's admin panel to easily add and manage books without needing to build everything from scratch.

Through this project, I practiced the basics of backend web development using Python and Django. I learned how to design a database, connect different parts of a system, and display data on a web page. I also used HTML for the pages and GitHub to store and manage the project.

Overall, Neo Library is a beginner-friendly project that helped me understand how real web applications are structured. It's still simple, but it shows how different parts of a system come together to build something functional.
