

To Do List is a web application I built using Django 6 to act like a task management system. It lets you create, update, and delete tasks, and also organise them by priority, category, and due dates. The idea was to create something that feels like a real productivity tool, where tasks are properly structured and easy to manage with a clean, modern interface.

The project works by using Django's class-based views structure of models, views, and templates. The Task model handles the data, including title, description, priority levels (Low, Medium, High), seven category types, due dates, and completion status. The views are responsible for listing tasks with advanced filtering by status, priority, category, assigned group, and keyword search, while the templates are the HTML pages that display everything in the browser. I also used Django's built-in authentication system to support user login, logout, and signup, along with Django's Groups framework to create customisable user groups like Supervisor, Worker, and Manager, so tasks can be assigned to specific users or entire teams.

Through this project, I practiced the basics of full-stack web development using Python and Django. I learned how to design a database with foreign key relationships to Django's User and Group models, connect different parts of a system with class-based views, and display data on responsive web pages styled with Tailwind CSS via CDN. I also integrated the `django-import-export` package to enable bulk data operations across CSV, JSON, and XLSX formats, and used GitHub to store and manage the project with version control.

Overall, To Do List is a beginner-friendly project that helped me understand how real web applications are structured with user authentication, role-based access, and data import/export capabilities. It's still simple, but it shows how different parts of a Django system come together to build something functional and user-friendly.
